

Bipartite Entanglement

Edward Kim

March 21, 2021

We first announce some proofs and arguments from Watrous as exercises, pillaging from his notation.

1 Separability

We start with the definition of separable operators. Throughout this section, let \mathcal{X}, \mathcal{Y} be finite-dimensional complex Hilbert spaces with $\mathcal{L}(\mathcal{X}), \mathcal{L}(\mathcal{Y})$ the spaces of linear operators for \mathcal{X}, \mathcal{Y} respectively.

Definition 1. *Let $P \in \mathcal{PSD}(\mathcal{X} \otimes \mathcal{Y})$ be a positive semi-definite operator. P is a separable operator if there exists a family of operators $\{X_a \mid a \in \Sigma\} \subset \mathcal{L}(\mathcal{X})$ and $\{Y_a \mid a \in \Sigma\} \subset \mathcal{L}(\mathcal{Y})$ and an indexing alphabet Σ such that*

$$P = \sum_{a \in \Sigma} X_a \otimes Y_a$$

Denote the set of all such separable operators over $\mathcal{X} \otimes \mathcal{Y}$ as $Sep(\mathcal{X} : \mathcal{Y})$. It's simple to see that $Sep(\mathcal{X} : \mathcal{Y})$ is a convex set by observing that if $P_0, P_1 \in Sep(\mathcal{X} : \mathcal{Y})$, then $P_0 + P_1 \in Sep(\mathcal{X} : \mathcal{Y})$. Similarly if $\lambda > 0$ is a real number, then $\lambda P_0 \in Sep(\mathcal{X} : \mathcal{Y})$. Thus, for $\lambda \in [0, 1]$

$$\lambda P_0 + (1 - \lambda) P_1 \in Sep(\mathcal{X} : \mathcal{Y})$$

showing convexity as desired.

There are several methods to express *separable states* i.e members of $SepD(X : Y) = Sep(X : Y) \cap \mathcal{D}(\mathcal{X} \otimes \mathcal{Y})$ as the following theorem states:

Theorem 1. *Let $\rho \in \mathcal{D}(\mathcal{X} \otimes \mathcal{Y})$ be an arbitrary state. The following statements are equivalent:*

1. $\rho \in SepD(X : Y)$
2. *There exists collections of states $\{\alpha_a \mid a \in \Sigma\} \subset \mathcal{D}(\mathcal{X})$, $\{\beta_a \mid a \in \Sigma\} \subset \mathcal{D}(\mathcal{Y})$ such that*

$$\rho = \sum_{a \in \Sigma} p(a) \alpha_a \otimes \beta_a$$

where Σ is an indexing alphabet and p is a probability distribution across Σ .

3. *There exists collections of unit vectors $\{x_a \mid a \in \Sigma\} \subset \mathcal{X}$, $\{y_a \mid a \in \Sigma\} \subset \mathcal{Y}$ such that*

$$\rho = \sum_{a \in \Sigma} p(a) x_a x_a^* \otimes y_a y_a^*$$

where Σ is an indexing alphabet and p is a probability distribution across Σ .

The Peres-Horodecki Criterion provides a useful criterion for determining the separability of operators:

Theorem 2. *(Peres-Horodecki) Let $P \in \mathcal{PSD}(\mathcal{X} \otimes \mathcal{Y})$ be a positive semi-definite operator. Then the following statements are equivalent:*

1. $P \in Sep(\mathcal{X} : \mathcal{Y})$
2. *For every choice of complex finite-dimensional Hilbert space \mathcal{Z} and positive map $\Phi : \mathcal{L}(\mathcal{L}(\mathcal{X}), \mathcal{L}(\mathcal{Z}))$,*

$$(\Phi \otimes \mathbb{I}_{\mathcal{L}(\mathcal{Y})})(P) \in \mathcal{PSD}(\mathcal{Z} \otimes \mathcal{Y})$$

3. *For every choice of complex finite-dimensional Hilbert space \mathcal{Z} and positive, unital map $\Phi : \mathcal{L}(\mathcal{L}(\mathcal{X}), \mathcal{L}(\mathcal{Z}))$,*

$$(\Phi \otimes \mathbb{I}_{\mathcal{L}(\mathcal{Y})})(P) \in \mathcal{PSD}(\mathcal{Z} \otimes \mathcal{Y})$$

2 Werner States

We start with definitions to ensure the notes are self-contained. Define

$$\begin{aligned}\Delta_0 &= \frac{1}{n} \sum_{a,b \in \Sigma} E_{a,b} \otimes E_{a,b} \\ \Delta_1 &= \mathbb{I}_{\mathcal{X}} \otimes \mathbb{I}_{\mathcal{Y}} - \Delta_0 \\ \Pi_0 &= \Pi_{\wedge^n \mathcal{X}} = \frac{1}{2}(\mathbb{I}_{\mathcal{X}} \otimes \mathbb{I}_{\mathcal{Y}} + \mathcal{F}) \\ \Pi_1 &= \mathbb{I}_{\mathcal{X}} \otimes \mathbb{I}_{\mathcal{Y}} - \Pi_0 = \Pi_{\vee^n \mathcal{X}} = \frac{1}{2}(\mathbb{I}_{\mathcal{X}} \otimes \mathbb{I}_{\mathcal{Y}} - \mathcal{F})\end{aligned}$$

3 Nielsen's Theorem

One way we can understand entanglement is through classes of operations which preserve entanglement. To be specific, recall that LOCC (*Local Operations with Classical Communication*) operations preserve entanglement as convex combinations of unitaries don't change the entanglement entropy of a state. This induces equivalence classes where members can be transformed into each other through LOCC operations. Nielsen's Theorem provides insight into the exact criterion for determining membership of equivalence classes:

Definition 2. Let $\rho, \gamma \in \mathcal{D}(\mathcal{X})$ be two states in \mathcal{X} . Let $\lambda_{\rho,i}, \lambda_{\gamma,i}$ be the spectra of ρ, γ respectively ordered in non-decreasing order. We say that γ majorizes ρ ($\rho \prec \gamma$) iff

$$\sum_{i=1}^k \lambda_{\rho,i} \leq \sum_{i=1}^k \lambda_{\gamma,i}$$

for all $k \in \{1, \dots, \dim \mathcal{X}\}$

Theorem 3. Let $u, v \in \mathcal{X} \otimes \mathcal{Y}$ be unit vectors. The following statements are equivalent:

1. $\text{Tr}_{\mathcal{Y}}(uu^*) \prec \text{Tr}_{\mathcal{Y}}(vv^*)$
2. There exists collections of operators $\{U_a \mid a \in \Sigma\} \subset \mathcal{U}(\mathcal{X})$ and $\{B_a \mid a \in \Sigma\} \subset \mathcal{L}(\mathcal{X})$ for some indexing alphabet $a \in \Sigma$ such that

- $\sum_{a \in \Sigma} B_a^* B_a = \mathbb{I}_{\mathcal{Y}}$
- $vv^* = \sum_{a \in \Sigma} (U_a \otimes B_a)uu^*(U_a \otimes B_a)^*$

3. There exists a separable channel Φ such that $vv^* = \Phi(uu^*)$

4 PPT States

Consider the transpose map $T : \mathcal{L}(\mathcal{L}(\mathcal{X}), \mathcal{L}(\mathcal{Y}))$ with the following action:

$$T(X) = X^\top, \quad X \in \mathcal{L}(\mathcal{X})$$

As transposing does not alter the spectrum of X , T is a positive map. An important class of states are called the *PPT states* which have the following property: consider $\mathcal{PSD}(X \otimes Y)$ to be the set of all positive semi-definite operators on $\mathcal{X} \otimes \mathcal{Y}$. We say that $P \in \mathcal{PSD}(\mathcal{X} \otimes \mathcal{Y})$ is PPT if

$$(T \otimes \mathbb{I}_{\mathcal{Y}})(P) \in \mathcal{PSD}(\mathcal{X} \otimes \mathcal{Y})$$

In other words, taking the partial transpose in respect to \mathcal{X} preserves the positive semi-definiteness of P . Denote the set of all PPT operators as $PPT(\mathcal{X} : \mathcal{Y})$. We can naturally extend this to states by taking the intersection $PPT(\mathcal{X} : \mathcal{Y}) \cap \mathcal{D}(\mathcal{X} \otimes \mathcal{Y})$. We will first demonstrate a method of constructing PPT operators which are not separable.

Definition 3. An unextendible product base is defined by two sets of unit vectors

$$\{u_a \mid u_a \in \mathcal{X}, a \in \Sigma\}, \{v_a \mid v_a \in \mathcal{Y}, a \in \Sigma\}$$

indexed by alphabet Σ such that the following hold:

1. The $u_a \otimes v_a$ are pairwise orthogonal
2. $\mathcal{V} = \sum_{a \in \Sigma} u_a \otimes v_a$ forms a proper subspace of $\mathcal{X} \otimes \mathcal{Y}$
3. If $r \in \mathcal{X}, \ell \in \mathcal{Y}$ and $(r \otimes \ell) \perp \mathcal{V}$, then $r \otimes \ell = 0$.

Exercise. In Example 6.40 of Watrous details a construction of an unextendible product base for $\mathbb{C}^3 \otimes \mathbb{C}^3$. Use a similar technique to construct UPBs for higher dimensions.

Theorem 4. Let $\{u_1 \otimes v_1, u_2 \otimes v_2, \dots, u_m \otimes v_m\}$ be an unextendable product base for $\mathcal{X} \otimes \mathcal{Y}$ with $\mathcal{V} = \sum_{r=1}^m u_a \otimes v_a$ its associated subspace. Let

$$\Pi = \sum_{r=1}^m u_r u_r^* \otimes v_r v_r^*$$

be the projection matrix on \mathcal{V} . Then

$$I_{\mathcal{X}} \otimes I_{\mathcal{Y}} - \Pi \in PPT(X : Y) \setminus Sep(X : Y)$$

Proof. Observe first that

$$(T \otimes I_{\mathcal{L}(\mathcal{Y})})(\Pi) = \sum_{r=1}^m \overline{u_r} u_r^T \otimes v_r v_r^*$$

is another projection matrix by computing $((T \otimes I_{\mathcal{L}(\mathcal{Y})})(\Pi))^2 = (T \otimes I_{\mathcal{L}(\mathcal{Y})})(\Pi)$. Hence,

$$(T \otimes I_{\mathcal{L}(\mathcal{Y})})(\Pi) \leq I_{\mathcal{L}(\mathcal{X})} \otimes I_{\mathcal{L}(\mathcal{Y})}$$

since $I_{\mathcal{L}(\mathcal{X})} \otimes I_{\mathcal{L}(\mathcal{Y})} - (T \otimes I_{\mathcal{L}(\mathcal{Y})})(\Pi) \in \mathcal{PSD}(\mathcal{X} \otimes \mathcal{Y})$. Since the partial tranpose map fixes the identity, we reexpress the inequality above as:

$$(T \otimes I_{\mathcal{L}(\mathcal{Y})})(I_{\mathcal{L}(\mathcal{X})} \otimes I_{\mathcal{L}(\mathcal{Y})} - \Pi) \in \mathcal{PSD}(\mathcal{X} \otimes \mathcal{Y}) \quad (1)$$

Since $I_{\mathcal{L}(\mathcal{X})} \otimes I_{\mathcal{L}(\mathcal{Y})} - \Pi \in \mathcal{PSD}(\mathcal{X} \otimes \mathcal{Y})$, it immediately follows that $I_{\mathcal{L}(\mathcal{X})} \otimes I_{\mathcal{L}(\mathcal{Y})} - \Pi$ must be contained in $PT(\mathcal{X} : \mathcal{Y})$.

To show separability, we argue through contradiction. To this end, suppose $I_{\mathcal{L}(\mathcal{X})} \otimes I_{\mathcal{L}(\mathcal{Y})} - \Pi$ is separable. By definition, this shows that we can deduce the equality:

$$I_{\mathcal{L}(\mathcal{X})} \otimes I_{\mathcal{L}(\mathcal{Y})} - \sum_{r=1}^m u_r u_r^* \otimes v_r v_r^* = \sum_{a \in \Sigma} x_a x_a^* \otimes y_a y_a^* \quad (2)$$

for some indexing alphabet Σ and unit vectors $x_a \in \mathcal{X}, y_a \in \mathcal{Y}$ for all $a \in \Sigma$. Multiplying both sides as follows to show that

$$\sum_{r=1}^m (u_r \otimes v_r)^* (I_{\mathcal{L}(\mathcal{X})} \otimes I_{\mathcal{L}(\mathcal{Y})} - \Pi) (u_r \otimes v_r) = \sum_{r=1}^m \sum_{a \in \Sigma} |\langle u_r \otimes v_r, x_a \otimes y_a \rangle|^2$$

The left side will trivially be zero by definition of Π , leaving the right-hand side to vanish:

$$\sum_{r=1}^m \sum_{a \in \Sigma} |\langle u_r \otimes v_r, x_a \otimes y_a \rangle|^2 = 0$$

Since the sum of nonnegative reals vanish, it must be that

$$\langle u_r \otimes v_r, x_a \otimes y_a \rangle = 0 \quad (3)$$

for all $r \in [m]$ and $a \in \Sigma$

Set $\mathcal{H} = \sum_{a \in \Sigma} x_a \otimes y_a$. By (3) above, \mathcal{H} forms a complementary orthogonal subspace to \mathcal{V} . Since \mathcal{V} is unextendible, $\mathcal{H} = 0$. In particular, $x_a \otimes y_a = 0$ for all $a \in \Sigma$. Substituting this into (2) yields that

$$\Pi = \mathbb{I}_{\mathcal{X}} \otimes \mathbb{I}_{\mathcal{Y}}$$

which contradicts the proper containment of \mathcal{V} . \square

Now that we have shown that there exist entangled PPT states, we can show that these states are still close to separable states in the sense that PPT states have no distillable entanglement. Let us start with a proposition which suggests that PPT states far away from maximally entangled states in terms of their fidelity:

Proposition 1. *Let $A \in \mathcal{L}(\mathcal{Y}, \mathcal{X})$ be an operator such that $\|A\| \leq 1$. Let $P \in PPT(X : Y)$. Then the following inequality must hold:*

$$\langle \text{vec}(A) \text{vec}(A)^*, P \rangle \leq \text{Tr}(P) \quad (4)$$

Proof. It is simple to show that the tranpose map is its own adjoint and inverse. Using this fact, it must hold that

$$\langle \text{vec}(A) \text{vec}(A)^*, P \rangle = \langle \text{vec}(A) \text{vec}(A)^*, (T \otimes I_{\mathcal{L}(\mathcal{Y})})(T \otimes I_{\mathcal{L}(\mathcal{Y})})(P) \rangle \quad (5)$$

$$= \langle (T \otimes I_{\mathcal{L}(\mathcal{Y})}) \text{vec}(A) \text{vec}(A)^*, (T \otimes I_{\mathcal{L}(\mathcal{Y})})(P) \rangle \quad (6)$$

Recall the vectorization identity

$$\text{vec}(ABC^T) = (A \otimes C) \text{vec}(B)$$

for any operators $A, B, C \in \mathcal{L}(\mathcal{Y}, \mathcal{X})$. Manipulating this identity for our case shows that

$$\text{vec}(A) \text{vec}(A)^* = (I_{\mathcal{X}} \otimes A^T) \text{vec}(I_{\mathcal{X}}) \text{vec}(I_{\mathcal{X}})^* (I_{\mathcal{X}} \otimes \overline{A})$$

Through a direct calculation, we deduce that

$$(T \otimes I_{\mathcal{L}(\mathcal{Y})})(\text{vec}(A)\text{vec}(A)^*) = (I_{\mathcal{X}} \otimes A^\top)(T \otimes I_{\mathcal{L}(\mathcal{X})})(\text{vec}(I_{\mathcal{X}})\text{vec}(I_{\mathcal{X}})^*)(I_{\mathcal{X}} \otimes \bar{A}) \quad (7)$$

$$= (I_{\mathcal{X}} \otimes A^\top)\mathcal{F}(I_{\mathcal{X}} \otimes \bar{A}) \quad (8)$$

where $\mathcal{F} : \mathcal{X} \otimes \mathcal{X} \rightarrow \mathcal{X} \otimes \mathcal{X}$ is the swap operator. Since \mathcal{F} is unitary, $\|\mathcal{F}\| \leq 1$. Combining this with the assumption that $\|A\| \leq 1$ shows that:

$$\|(T \otimes I_{\mathcal{L}(\mathcal{Y})})(\text{vec}(A)\text{vec}(A)^*)\| \leq \|(I_{\mathcal{X}} \otimes A^\top)\| \cdot \|\mathcal{F}\| \cdot \|(I_{\mathcal{X}} \otimes \bar{A})\| \leq 1$$

By Holder inequality for Schatten norms, $(|\langle B, A \rangle| \leq \|B\|_p \|A\|_{p^*})$ for $p, p^* \in [1, \infty]$ dual to each other)

$$\begin{aligned} \langle (T \otimes I_{\mathcal{L}(\mathcal{Y})})(\text{vec}(A)\text{vec}(A)^*), (T \otimes I_{\mathcal{L}(\mathcal{Y})})(P) \rangle &\leq \|(T \otimes I_{\mathcal{L}(\mathcal{Y})})(\text{vec}(A)\text{vec}(A)^*)\| \cdot \|(T \otimes I_{\mathcal{L}(\mathcal{Y})})(P)\|_1 \\ &\leq \|(T \otimes I_{\mathcal{L}(\mathcal{Y})})(P)\|_1 \end{aligned}$$

The final step simply recognizes that $\|(T \otimes I_{\mathcal{L}(\mathcal{Y})})(P)\|_1 = \text{Tr}(P)$ since $P \in \mathcal{PSD}(\mathcal{X} \otimes \mathcal{Y})$ and transpose preserves the trace of P . By finally combining this with the above observations, we get the desired inequality. \square

5 Correlation Operators
